Stage 1 — Closed lobes: the ellipse phase

Norm conic deg(m − nF) = m² − a·mn + q·n² for 11a1 at p = q = 5, a = 1. Blue: the level ellipse deg = 4.

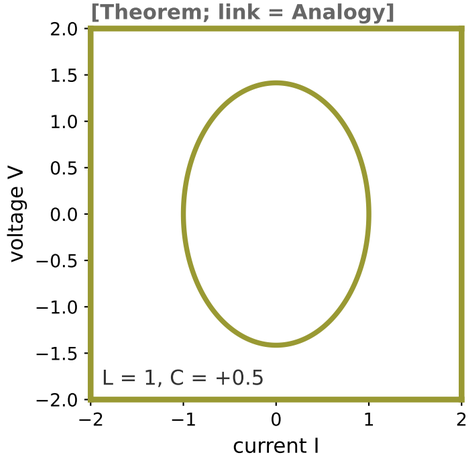

Tangent intercepts carry the phase
intercept = −h*(slope)
[Theorem]

F and V: roots of x² − ax + q
[Theorem]

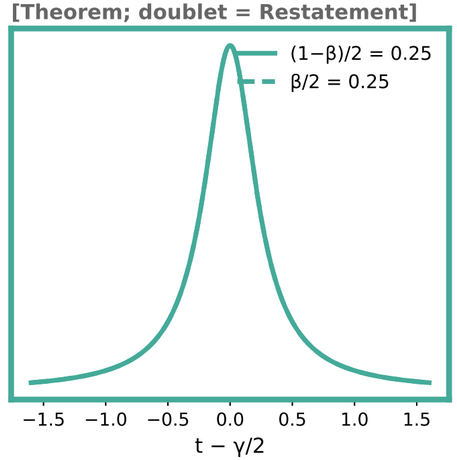

Closed lobe = the Hasse bound
$a^2 < 4q \Leftrightarrow V = \bar{F} \Leftrightarrow |\alpha| = \sqrt{q}$
[Theorem for curves]

LC energy: ellipse
[Theorem; link = Analogy]

Resonance doublet (on the line)
[Theorem; doublet = Restatement]

Every disk: Critical line (y-axis) · Nested rings (weight strata) · Origin ↔ infinity (the cusp)

Colours = concepts (see legend.png); grey [badge] = status. No null rays at 45° (per J. W. McGreevy); lobes are elliptical conic sections, not elliptic curves.

After J. W. McGreevy's animation 'Flat Potential Oscillations' (Aug 2025, x.com/McGreevyMD/status/1951474097990279331). Re-rendered by Grok Bot from the analysed geometry; not J. W. McGreevy's code. RH is not proved.
